# Exp 5.SVC API

## sklearn.svm.SVC

```
class sklearn.svm.SVC(*, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', break_ties=False, random_state=None)
```

Parameters:

**C** - Regularization parameter.

**Kernel** - Specifies the kernel type to be used in the algorithm

**Degree** - Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**Gamma** - Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

**coef0** - Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**Shrinking** - Whether to use the shrinking heuristic.

**Probability** - Whether to enable probability estimates

**class\_weight** - Whether we want to assign weights to our classes

**max\_iter** - Limit on the number of iterations of the solver

**decision\_function\_shape** - One versus rest or one versus one method to solve in case of multi class classification

**random\_state** - Numpy seed to be used while generating random numbers

## Attributes

**class\_weight\_** - Multipliers of parameter C for each class. Computed based on the `class_weight` parameter.

**classes\_** - Class labels

**coef\_** - Weights assigned to the features

**dual\_coef\_** - Dual coefficients of the support vector in the decision function multiplied by their targets. For multiclass, coefficient for all 1-vs-1 classifiers.

**fit\_status\_** 0 if correctly fitted, 1 otherwise (will raise warning)

**intercept\_** - Constants in decision function.

**support\_** - Indices of support vectors.

**support\_vectors\_** - Support vectors.

**n\_support\_** - Number of support vectors for each class.

## Methods

<b>decision_function</b> (X)	Evaluates the decision function for the samples in X.
<b>fit</b> (X, y[, sample_weight])	Fit the SVM model according to the given training data.
<b>get_params</b> ([deep])	Get parameters for this estimator.
<b>predict</b> (X)	Perform classification on samples in X.
<b>score</b> (X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
<b>set_params</b> (**params)	Set the parameters of this estimator.

## How sklearn handles SVM?

- Support vector machines (SVMs) are a set of supervised learning methods used for classification, regression and outliers detection.
- The advantages of support vector machines are:
  - i. Effective in high dimensional spaces.
  - ii. Still effective in cases where number of dimensions is greater than the number of samples.
  - iii. Uses a subset of training points in the decision function (called support vectors), so it is also memory efficient.
  - iv. Versatile: different Kernel functions can be specified for the decision function. Common kernels are provided, but it is also possible to specify custom kernels.
- The disadvantages of support vector machines include:
  - i. If the number of features is much greater than the number of samples, avoid over-fitting in choosing Kernel functions and regularization term is crucial.
  - ii. SVMs do not directly provide probability estimates, these are calculated using an expensive five-fold cross-validation.
- The support vector machines in scikit-learn support both dense (numpy.ndarray and convertible to that by numpy.asarray) and sparse (any scipy.sparse) sample vectors as input.
- However, to use an SVM to make predictions for sparse data, it must have been fit on such data.
- For optimal performance, use C-ordered numpy.ndarray (dense) or scipy.sparse.csr\_matrix (sparse) with dtype=float64.
